

***Contra Costa's experience with  
Low Impact Development  
for***

**Stormwater  
Treatment and Flow  
Control**

Dan Cloak, P.E.  
*California Water Environment Association P3S Conference*  
February 28, 2007

## Outline

- Key insights into HMP requirements
- LID Design Procedures
- LID Design Details
- Example Site Designs
- Continuous Improvement of Contra Costa's Approach
- Applicability to other regions

## What the permit requires

*... post-project runoff discharge rates and durations shall not exceed estimated pre-project discharge rates and durations where the increased discharge rates and durations will result in increased potential for erosion or other significant adverse impacts to beneficial uses...”*

## Insights from watershed analysis

- Most streams are incised and/or are already experiencing accelerated erosion.
- Geomorphic assessment has a variety of methods, and conclusions differ.
- Local government lacks the resources to conduct a comprehensive analysis of all stream reaches in the County.
- Extrapolating hydrologic characteristics from watershed to site (or from site to watershed) requires guesswork.

## **Contra Costa HMP Strategy**

- Accept a presumptive standard that developments must match pre-project flows
- Assist developers with the technical means to comply with that standard
- Promote Low Impact Development (LID)
- Provide developers with options

## Options for HMP Compliance

1. Show project does not increase total amount of impervious area
2. Use Low Impact Development Integrated Management Practices
3. Use a continuous-simulation model to show runoff will not exceed pre-project flow peaks and durations
4. Show projected increases in runoff peaks and durations will not accelerate erosion of receiving stream

## LID Site Design

- Divide the site into Drainage Management Areas
- Use landscape to disperse and retain runoff where possible
- Route drainage from remaining areas to IMPs
- Design the IMPs to accommodate available space and hydraulic head

# Drainage Management Areas

- Four Types of Areas
  - Self-treating areas
  - Self-retaining areas
  - Areas draining to a self-retaining area
  - Areas draining to an IMP
- Only one surface type within each area
- Many-to-one relationship between drainage areas and IMPs

## Self-treating areas

- Must be 100% pervious
- Must drain offsite
- Must not drain on to impervious areas
- Must not receive drainage from impervious areas
- Must not drain to IMPs
- No treatment or flow control required
- No further calculations required

# Self-retaining areas

## **Self-retaining areas**

- Berm or depress grade to retain 1" rain
- Set area drain inlets above grade
- Amend soils
- Terrace mild slopes
- Have limited applicability in
  - Dense developments
  - Hillsides

## Areas draining to self-retaining areas

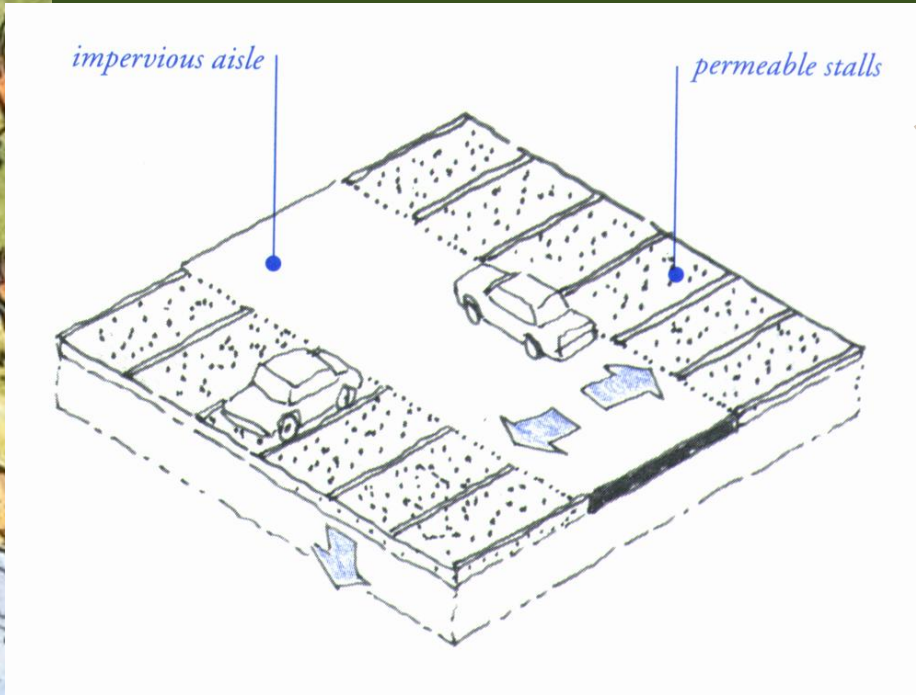

- Impervious areas can drain on to self-retaining areas
- Example: Roof leaders directed to lawn or landscape
- Maximum ratio is 1:1 impervious:pervious if flow control requirements apply to project
- Maximum ratio is 2:1 if treatment only requirements apply to project
- No maintenance verification required

# Areas draining to self-retaining areas

$$\frac{\text{Impervious}}{\text{Pervious}} \leq 1$$

## **Areas draining to IMPs**

- Areas used to calculate the required size of the IMP
- Where possible, drain only impervious roofs and pavement to IMPs
- Delineate any pervious areas separately
- Use the sizing tool

# Integrated Management Practices

## Advantages

- Detain and treat runoff
- Typically fit into setbacks and landscaped areas
- Accommodate diverse plant palettes
- Low-maintenance
- Don't breed mosquitoes
- Can be attractive

## Challenges

- Soil surface must be 6-12" lower than surrounding pavement
- Require 3-4 feet of vertical "head"
- Can affect decisions about placement of buildings, roadways, and parking

# Implementing LID IMPs

- IMPs can be effective, attractive, and accepted by developers
- Incorporate IMPs in preliminary site, landscaping and drainage design drawings

# Flow-through Planter

# In-ground Planter

# Vegetated Swale

# Bioretention Area

*(Prince George's County 1993)*

# Dry Well

# Infiltration Trench

# Infiltration Basin

# Size, depth and head

## ■ Size

- Determined by sizing factors
- Required dimensions should be shown on C.3 plan or grading and drainage plan

## ■ Depth

- Reservoir
- Soil Layer
- Drainage Layer

# LID and Hydraulic Head

Collect and convey

Disperse to landscape

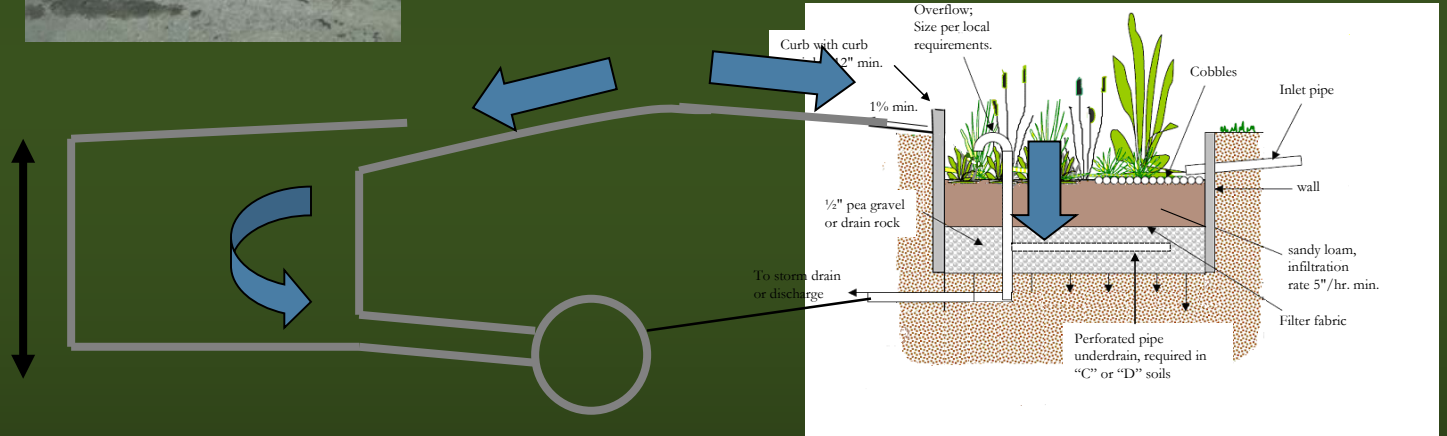

- Saves space
- Concentrates flows
- “Drop” at inlet
- Keeps flows dispersed
- Requires space
- “Drop” through soil filter

# LID and Head

**Watch  
your  
head**

# Fill Materials

- Soil layer
  - Infiltration rate  $\geq 5$ " / hour
  - Clay  $< 5\%$
  - Current spec:
    - 50-60% construction sand
    - 20-30% compost
    - 20-30% topsoil
  - Looking for a “branded” mix
- No filter fabric between layers
- Gravel drainage layer
  - “Class 2 Perm”
  - Caltrans Manual 68-1.025

# Inlets

# Overflows

# Install IMPs level

# Overflows

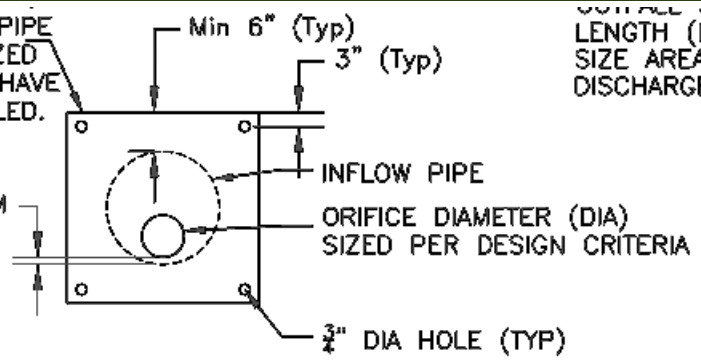

# Overflow

1) FT GREATER THAN PIPE  
 A. HOT-DIP GALVANIZED  
 PLATE AFTER HOLES HAVE  
 BEEN DRILLED.

MINIMUM SURFACE STRENGTH  
 LENGTH (L) X 1/4  
 SIZE AREA PER  
 DISCHARGE REQ

## FLOW CONTROL ORIFICE PLATE

# Example Site Designs

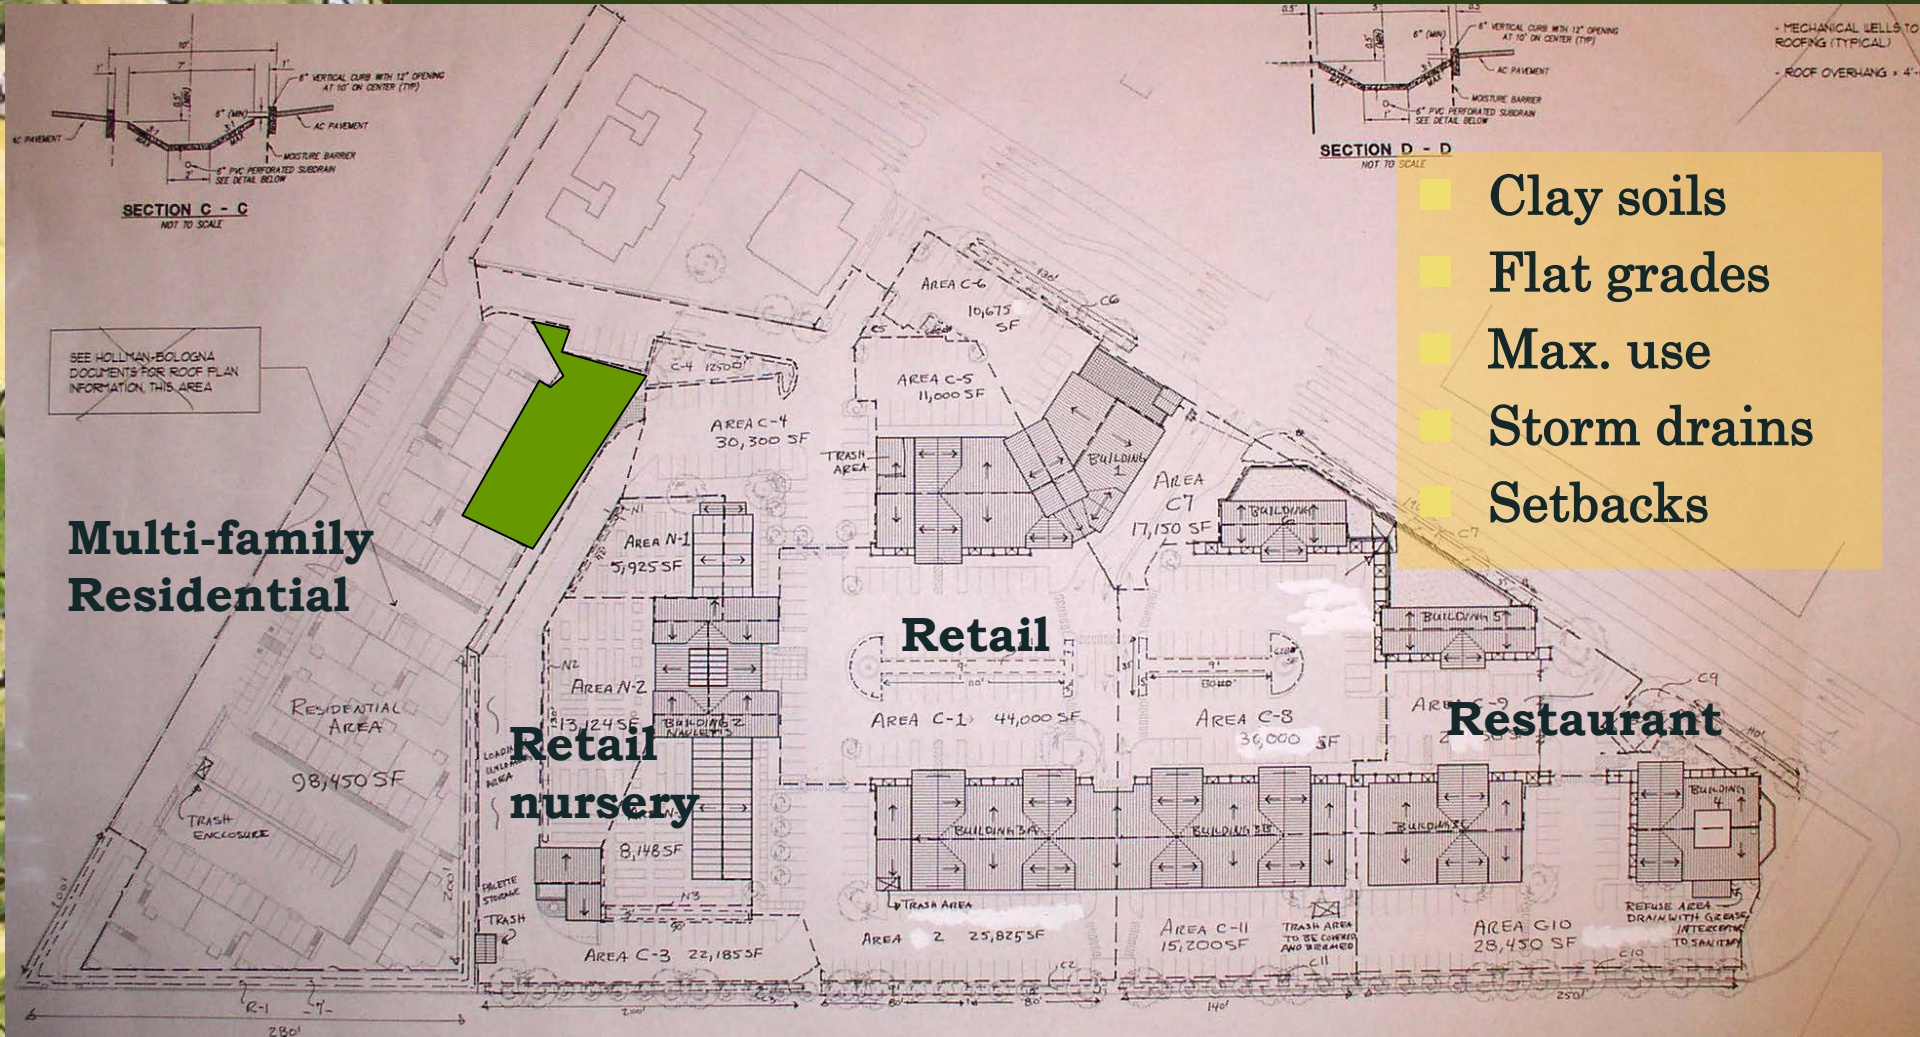

# Rose Garden

# 9-acre, mixed use

**Multi-family Residential**

**Retail nursery**

**Retail**

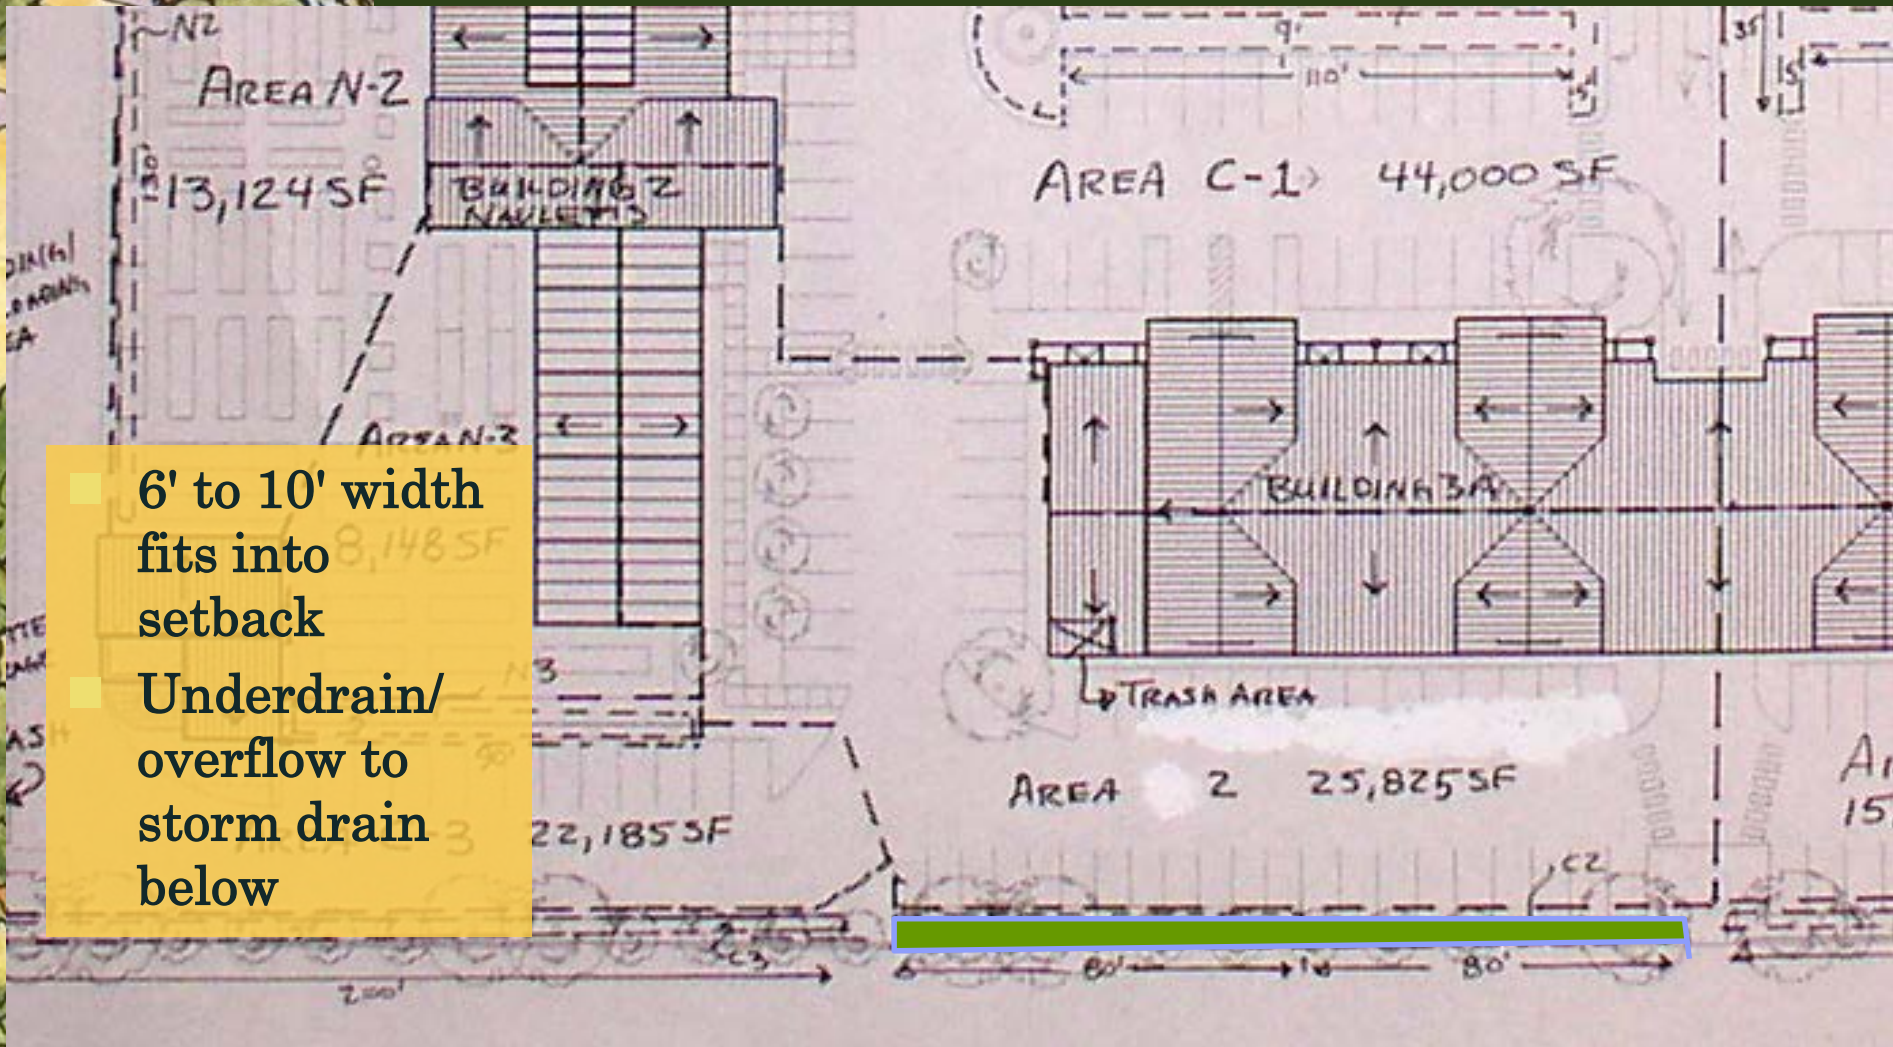

**Restaurant**

- Clay soils
- Flat grades
- Max. use
- Storm drains
- Setbacks

# Swale "C-2"

- 6' to 10' width fits into setback
- Underdrain/overflow to storm drain below

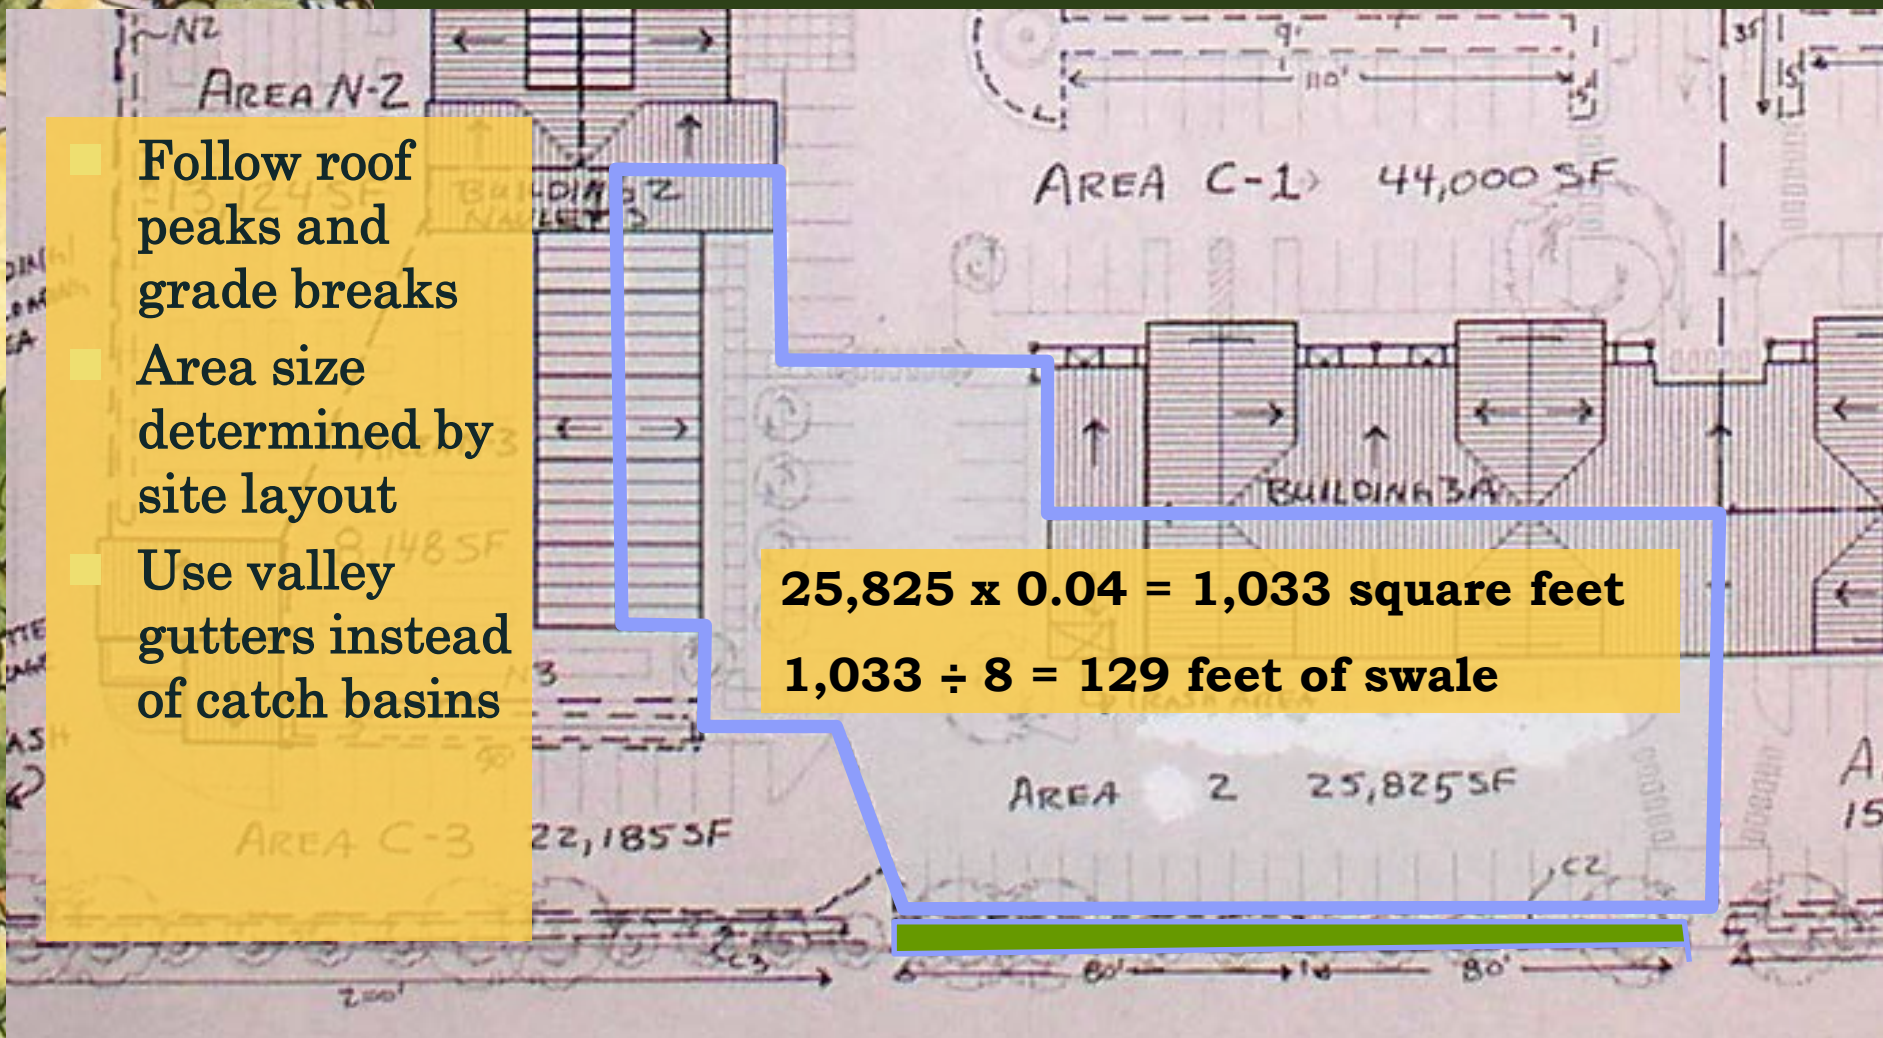

# Area "C-2"

- Follow roof peaks and grade breaks
- Area size determined by site layout
- Use valley gutters instead of catch basins

$$25,825 \times 0.04 = 1,033 \text{ square feet}$$
$$1,033 \div 8 = 129 \text{ feet of swale}$$

## Lessons

- Possible to incorporate stormwater treatment BMPs without sacrificing usable area
- Use roof plan *and* grading plan to draw drainage areas
- Overland drainage to BMPs can be a challenging design problem on flat sites

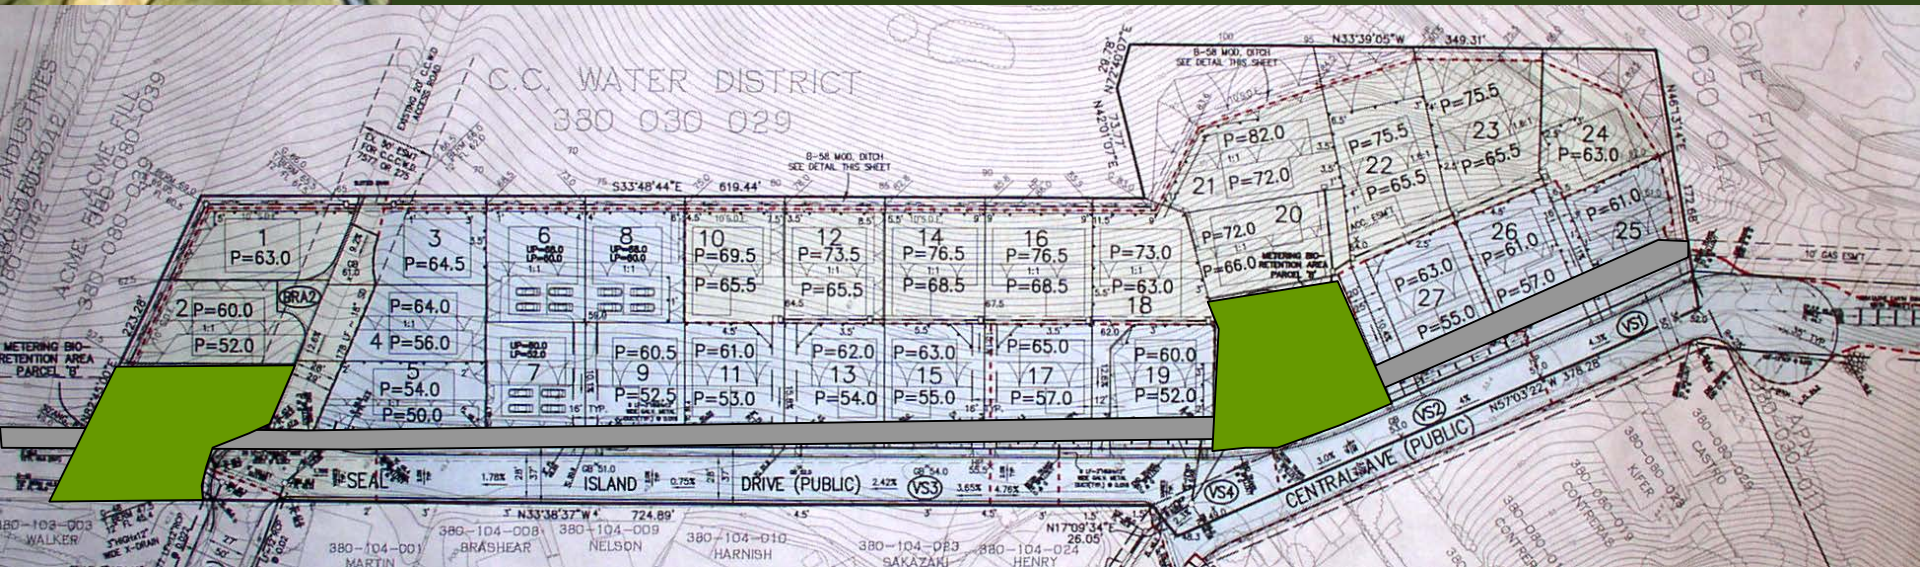

# Seal Island Estates

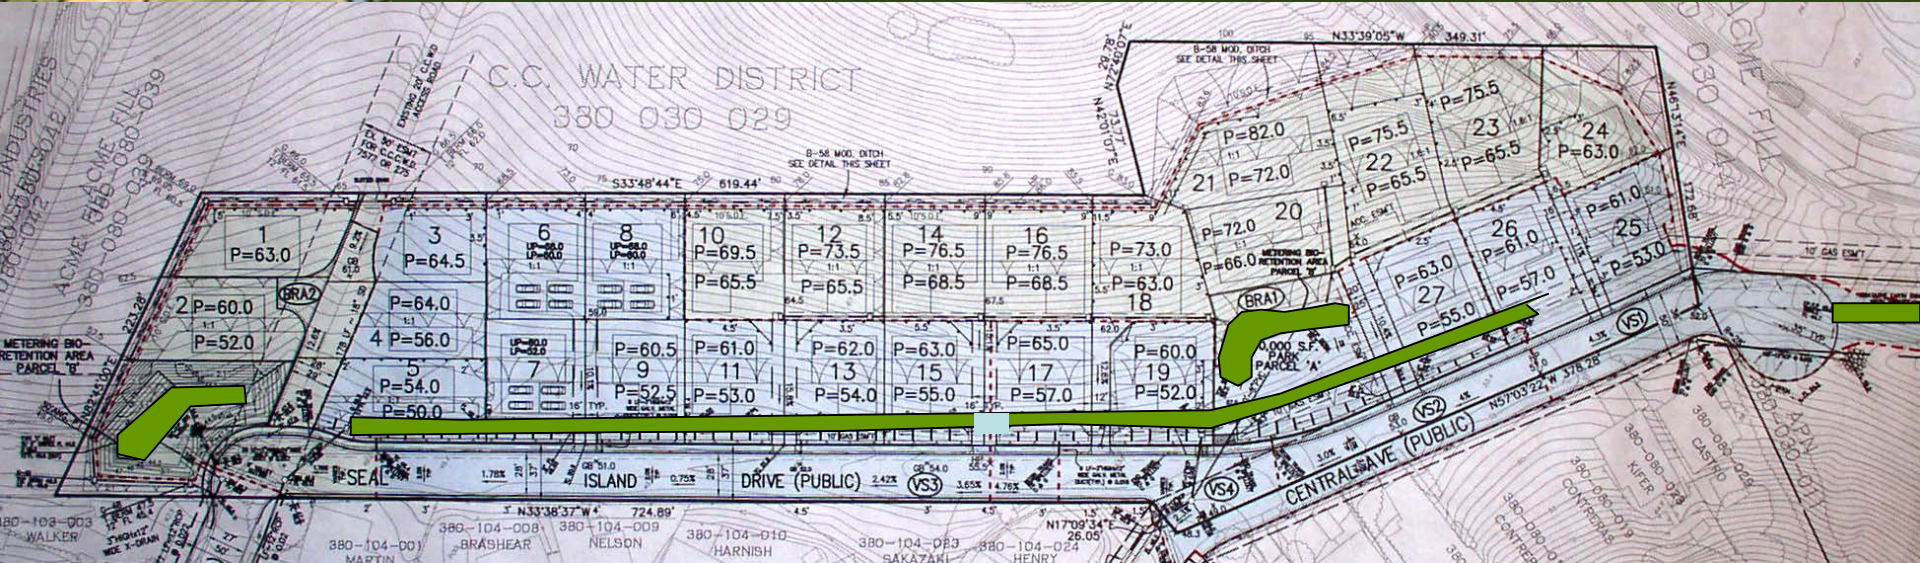

# 27 lots on a hillside

- Hillside
- Clay soils
- Steep driveways
- Undulating terrain
- New streets
- Pocket parks
- Pipeline easement
- Tentative Map

# 27 lots on a hillside

- Ditch upslope runoff around development
- Collect and pipe runoff from upper lots to bioretention area
- Cross-slope streets toward development
- How to provide for maintenance in perpetuity?

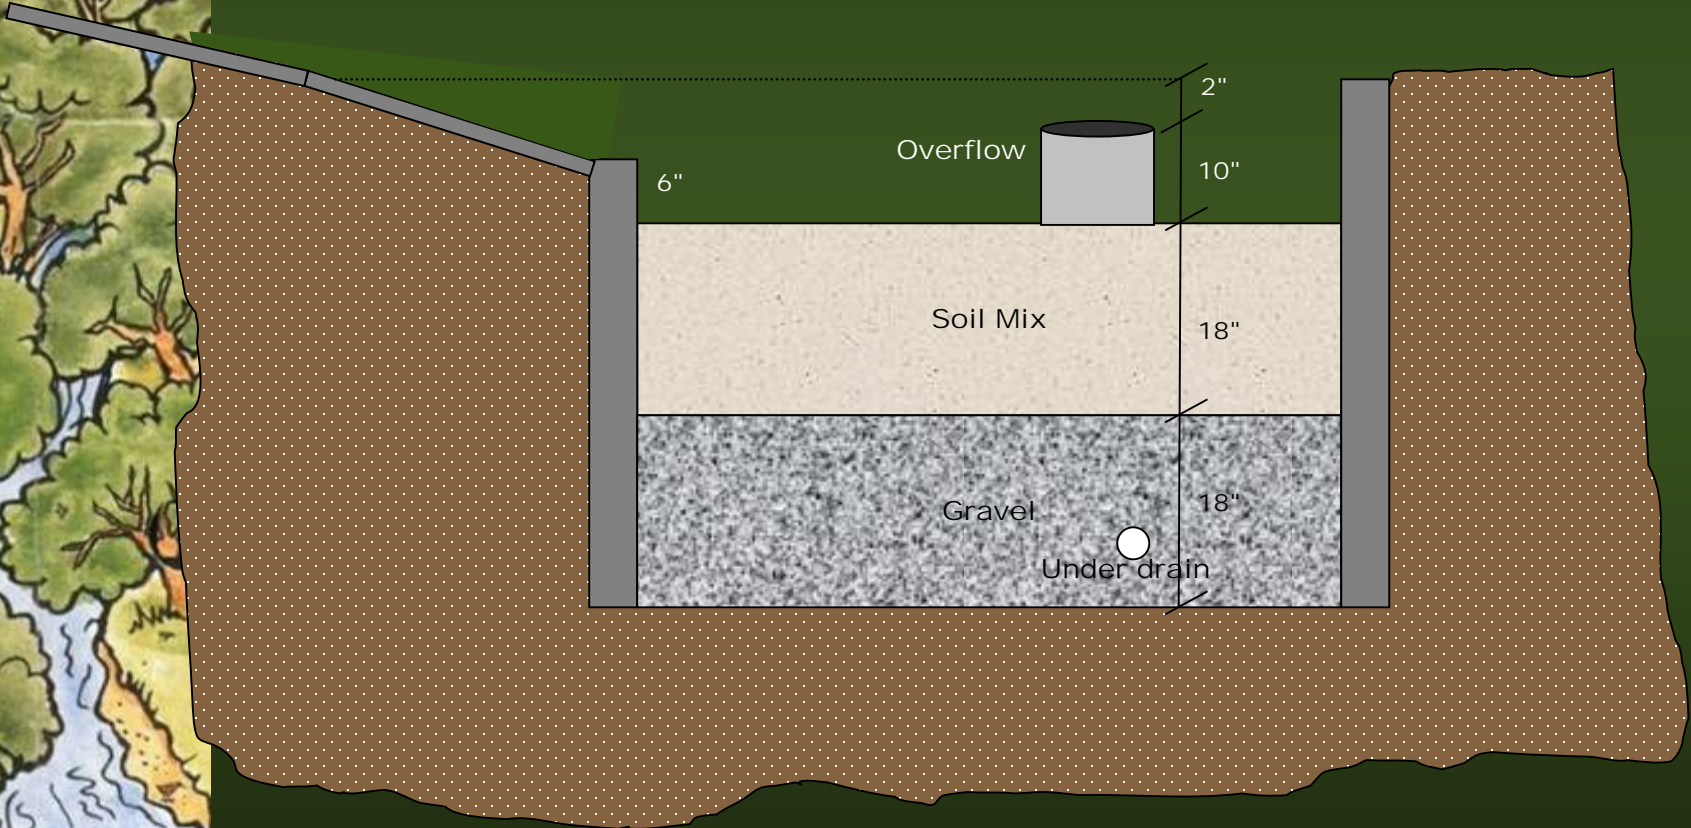

# Continuous Improvement

- More and better IMP designs
  - Smaller sizing factors
  - Safe and constructable
    - Fill materials and outflow details
  - Good-looking and salable
  - Engaging the development community
- Consistent application of requirements throughout Contra Costa County
- Validating modeled IMP outflows

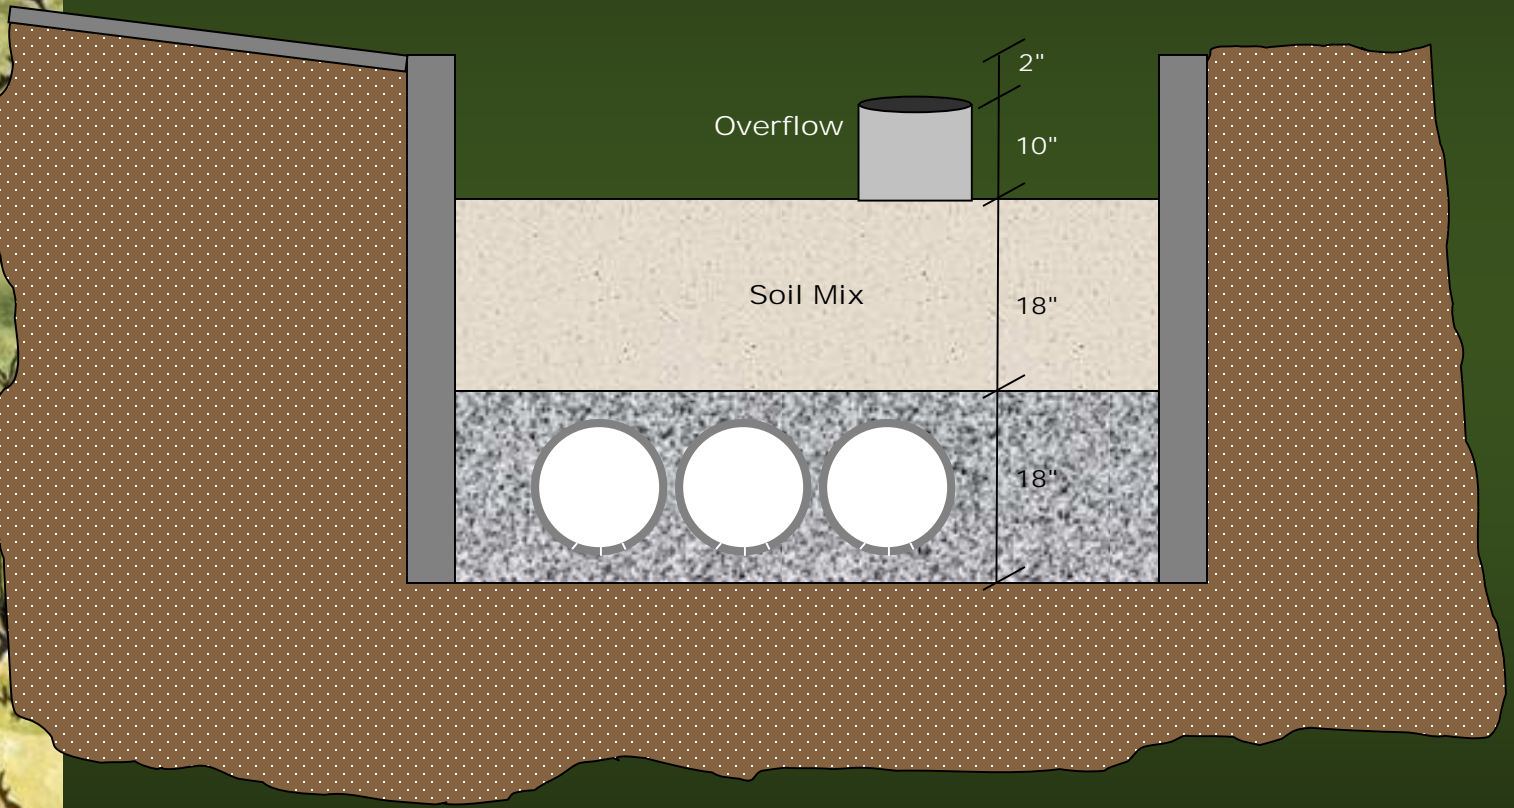

## Adapting to other regions

- Most aspects are the same:
  - Regulations are similar
  - Can use same suite of IMPs
  - Modeled stage-storage-discharge relationships are the same
  - *Stormwater C.3 Guidebook* format and “Stormwater Control Plan” submittal concept has already been reused in Sonoma and Alameda counties
- Would need to customize by:
  - Using local rainfall record to calculate regional sizing factors and adjustments
